Case of the Month:

85-year-old female with breast mass

Lisa Ho¹, MS4, Aden Weybright, Bing Han², MD, Angela Choe³, MD

¹Penn State College of Medicine, Hershey, PA, USA
²Department of Pathology
³Department of Radiology
Patient Presentation

85-year-old female presenting with a right breast mass that has been increasing in size, first noticed 8 months ago. She reports enlarging nipple and change in coloration of skin in upper outer breast. She denies any bleeding or pain relating to breast mass other than recent sensitivity in right axillary region. No history of prior breast problems.

Onset of menses at age 15, first live birth at age 19, P5 G5. She is postmenopausal, starting menopause in her 40s. No history of hormone replacement.
Pertinent History & Physical Exam

Family history: daughter with breast cancer at age 55, tested negative for any gene mutation

Social History: non-smoker, no alcohol

Physical exam: Right breast mass in upper outer quadrant with redness and enlargement of right nipple. No nipple discharge. No axillary lymphadenopathy.
What Imaging Should We Order?
A diagnostic mammogram with digital breast tomosynthesis (DBT) can address limitations encountered with standard mammographic views.

If mammogram findings are suspicious for malignancy, ultrasound may further characterize the lesion and detect additional lesions not evident on mammography or DBT.

**Variant 2:**

Palpable breast mass. Female, 40 years of age or older, mammography findings suspicious for malignancy. Next examination to perform. (See Appendix 1A for additional steps in the workup of these patients.)

Diagnostic Mammogram and Ultrasound Right Breast
(not labeled)
Coarse heterogenous calcifications with grouped distribution

High density, irregular mass with indistinct margins

Skin thickening and nipple retraction

Not parallel orientation

Coarse heterogenous calcifications with grouped distribution

Microlobulated margins, Hypoechoic relative to adipose tissue

Diagnostic Mammogram and Ultrasound Right Breast
Differential Diagnosis (based on imaging)

1. Invasive Lobular Carcinoma
2. Metastatic Carcinoma
3. Inflammatory Carcinoma
4. Metaplastic Carcinoma

What should be done next?
Ultrasound Guided Core Biopsy & Diagnostic Post Clip Mammogram

Biopsy site

Biopsy Clip
H&E stain: Magnified view of core biopsy tissue showing tumor cells distributed in nests with keratinized pearls

Receptor testing: ER negative, PR negative, Her2 negative
H&E stain: Magnified view of mastectomy tissue consistent with metaplastic carcinoma of the breast. The absence of dysplasia in skin adjacent to the tumor supports that this is a breast, not cutaneous, primary.
Final Diagnosis:

Metaplastic Breast Carcinoma (squamous type)
Metaplastic breast carcinoma (MpBC) is an uncommon type of neoplasia

- Accounts for less than 1% of breast carcinomas, and mostly appear in postmenopausal women
- May appear sporadically or derive from preexistent lesions involving breast glandular and tubular structures (adenomyoepithelioma, complex sclerosing lesions, fibrocystic disease)
- Usually appears as a palpable mass in the breast that grows rapidly and has high density on mammograms
- Most tumors of the breast arise from epithelium; however, the epithelium can differentiate into mesenchymal tissue which is a process called metaplasia
- Is typically associated with triple-negative breast cancer (TNBC) lacking ER, PR, and HER2 hormone receptors
MpBC has several morphological categories that differ in clinical prognosis

World Health Organization (WHO) classification system of MpBC based on histological organization:

- low-grade adenosquamous carcinoma
- fibromatosis-like metaplastic carcinoma
- squamous cell carcinoma
- spindle cell carcinoma
- carcinoma with mesenchymal differentiation

All of these metaplastic variants are aggressive, chemoresistant, and have a high propensity to metastasize, with the exception of fibromatosis-like carcinoma and low-grade adenosquamous carcinoma.
With a widely variable oncology response, MpBC often requires a complex multidisciplinary treatment

- Due to the rarity and lack of homogeneity among MpBC tumor cells, a combination of conventional treatments including chemotherapy, surgery, and radiotherapy are often used\textsuperscript{6,7}

- MpBC recurs more often and more quickly compared to invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC), with a peak recurrence rate of 18 months to 3-5 years after treatment\textsuperscript{6,7}

- The prognosis for MpBC is often poor because of the cancer’s aggressive growth rate, high likelihood of metastasizing, and shorter disease-free and overall survival (OS) compared to non-metaplastic breast cancer\textsuperscript{6,8}
